Hereditary Thrombophilia

Hereditary thrombophilia is a genetic condition that increases the risk of developing abnormal blood clots (thrombosis) that can block blood flow in veins or arteries. Most people with hereditary thrombophilia never develop thrombosis.

Clark, you have two copies of a genetic variant we tested.

People with this number of copies of the variant have a reduced risk of this condition. Inheritance and risk effects from our data after your test.

Variant detected
in the F5 gene

1 copy is not considered
in this test

The test may not be able to determine if both copies of the variant are present. This can be caused by a deletion and can affect how the test interprets and risk level.

How To Use This Test

The first two are diagnoses hereditary thrombophilia and factor V Leiden thrombophilia.

These are conditions that can increase the risk of developing abnormal blood clots (thrombosis).

Review the Genetic Health Risk tutorial

See Scientific Details

See Frequently Asked Questions

Intended Uses

Use the Factor V Leiden variant in the F5 gene and the Prothrombin G20210A variant in the F2 gene to determine if a person has hereditary thrombophilia.

Limitations

- Does not test for all variants currently tested by hereditary thrombophilia.
- Does not test for all variants currently tested in the F5 gene and the F2 gene.

Important Effectives

- Most people with hereditary thrombophilia never develop blood clots.
- Most people in the general population with European ancestry, like African Americans and Europeans or Asians.

You have an **increased risk** of developing harmful blood clots based on your genetic result.

It is important to discuss the result with a healthcare professional.

We detected two copies of the Prothrombin G20210A variant in the F2 gene.
This is the most common variant in the F2 gene, which is more commonly found in people of European ancestry.

See Scientific Details

People with this result are more likely to develop harmful blood clots than those without the variant.
The risk is lower than the risk from Factor V Leiden. The type of event you are definitely more likely to develop and how often.

Since you share DNA with your family members, they may also be interested in this result.
Your family members may be at risk for developing harmful blood clots. Offering family tests of Factor V Leiden and sharing more in these steps of the process.

Lifestyle and other factors can also influence the chances of developing harmful blood clots.

Consult a healthcare professional to discuss these factors.

Major surgery
Hip or knee surgery

About Hereditary Thrombophilia

Hereditary thrombophilia is a genetic condition that increases the risk of developing abnormal blood clots (thrombosis) that can block blood flow in veins or arteries. Most people with hereditary thrombophilia never develop thrombosis.

When it develops
Hereditary thrombophilia, but the risk of developing thrombosis is highest during adulthood.

How common is the condition?
Factor V Leiden and the F2 G20210A variant are the most common inherited risk factors for thrombosis in people of European ancestry. Factor V Leiden affects about 5 in 100 people of European ancestry and is found in about 1 in 1,000 people of African ancestry and Asians. The F2 G20210A variant affects about 2 in 100 people of European ancestry and is found in about 1 in 1,000 people of African ancestry.

Typical signs and symptoms of harmful blood clots
- Pain, tenderness, swelling, or redness in one or both legs
- Chest pain
- Difficulty breathing
- Sudden vision changes or loss

How it is treated
Treatment for hereditary thrombophilia usually involves medicines called anticoagulants, which help prevent blood clots from forming or getting larger.

Scientific Details

Hereditary thrombophilia is a genetic condition that increases the risk of developing abnormal blood clots (thrombosis) that can block blood flow in veins or arteries. Most people with hereditary thrombophilia never develop thrombosis.

Hereditary thrombophilia is linked to variants in multiple genes.

The report includes one variant in the F5 gene and one variant in the F2 gene. The tests does not screen variants in other genes.

F5 | F2

The F5 gene contains instructions for making a protein called coagulation factor V. This protein plays a critical role in the blood clotting process. Variants in the F5 gene can cause hereditary thrombophilia.

Chromosome 1

Factor V

The F2 gene contains instructions for making a protein called prothrombin. This protein plays a critical role in the blood clotting process. Variants in the F2 gene can cause hereditary thrombophilia.

Chromosome 11

Factor II

You have two copies of a genetic variant we tested. Your result for the variant tested could not be determined.

Genetic Inheritance

How All Parent Matters

Factor V Leiden	Your Genotype	Genetic Inheritance
Variant Copies	Not determined	• Biological relationships • Typical vs. variant DNA sequences • Percent of Possible Inheritance with variant • References (1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12 links)

Prothrombin G20210A Variant	Your Genotype	Genetic Inheritance
Variant Copies	Not determined	• Biological relationships • Typical vs. variant DNA sequences • Percent of Possible Inheritance with variant • References (1, 13, 14, 15, 16, 17, 18, 19 links)

The F5 gene contains instructions for making a protein called coagulation factor V. This protein plays a critical role in the blood clotting process. Variants in the F5 gene can cause hereditary thrombophilia.

The F2 gene contains instructions for making a protein called prothrombin. This protein plays a critical role in the blood clotting process. Variants in the F2 gene can cause hereditary thrombophilia.

Test Interpretation

The report provides information for one variant in the F5 gene and one variant in the F2 gene. The test does not screen variants in other genes.

Factor V Leiden	Prothrombin G20210A	Likelihood	Odds ratio
Not determined	Not determined	Not determined	Not determined

The test could not determine if both copies of the variant are present. This can be caused by a deletion and can affect how the test interprets and risk level.

Variant	Decrease risk
Normal population	1 in 1,000
Two copies of Factor V Leiden variant	1 in 1,000
Two copies of Factor V Leiden variant	10 in 1,000
Two copies of Prothrombin G20210A variant	Not available
One Factor V Leiden variant and one Prothrombin G20210A variant	Not available

Other Factors

Other factors besides the variants included in the test can influence your chances of developing harmful blood clots.

Risk factors	Decrease risk
Major surgery	[1, 2, 3, 4, 5]
Major surgery requiring general anesthesia and lasting at least 30 minutes is associated with a significantly increased risk of developing harmful blood clots. Hip or knee surgery is associated with the highest risk.	
Prolonged immobility	[1, 2, 3, 4, 5]
Prolonged immobility, such as during a hospital stay or a long flight, increases the risk of developing harmful blood clots. Moving around as much as possible can help reduce the risk. Activities like the following are considered prolonged immobility.	
Oral contraceptives	[1, 2, 3, 4, 5]
Oral contraceptives or hormone replacement therapy have a small increased risk of developing harmful blood clots. Women who smoke and are over the age of 35 are at the highest risk.	
Obesity	[1, 2, 3, 4, 5]
Obesity can increase the risk of developing harmful blood clots.	
Pregnancy	[1, 2, 3, 4, 5]
Pregnancy increases the risk of developing harmful blood clots.	
Cancer	[1, 2, 3, 4, 5]
Cancer can increase the risk of developing harmful blood clots. Cancer treatments, such as chemotherapy, can also increase the risk.	
Smoking	[1, 2, 3, 4, 5]
Current smokers have a higher risk of developing harmful blood clots than non-smokers.	

Test Details

Indications for Use

The Ecoutis Hereditary Thrombophilia Test Report for Hereditary Thrombophilia is indicated for reporting of the Factor V Leiden (rs1800595) and the Prothrombin G20210A (rs1799963) variants in the F5 and F2 genes, respectively, from buccal swab DNA samples. The test is intended for use by healthcare professionals and their patients.

Special Considerations

- Testing for genetic variants associated with hereditary thrombophilia is recommended for all first-degree relatives of individuals who have been identified as carriers of a familial variant.

Test Performance Summary

Clinical Reference

- The Factor V Leiden variant is reported to be responsible for around 18% of all VTE events in the European population.
- The Prothrombin G20210A variant is reported to be responsible for around 6% of all VTE events in the European population.
- Other variants in other genes not tested may be more often associated with risk of developing thrombosis in other populations.

Analytical Performance

Ecoutis has observed 100% concordance during the test verification process between the results obtained from the Ecoutis Hereditary Thrombophilia Test and results obtained from orthogonal methods.

Warnings and Limitations

- The test does not cover all variants that are associated with thrombophilia.
- The test does not diagnose any health conditions.
- Consult with your healthcare professional before making medical decisions.
- If you are concerned about your results, contact your healthcare professional.

See the Testing Limits for more details on test limitations.

See the Frequently Asked Questions for more information.

Frequently Asked Questions

Hereditary thrombophilia is a genetic condition that increases the risk of developing abnormal blood clots (thrombosis) that can block blood flow in veins or arteries. Most people with hereditary thrombophilia never develop thrombosis.

Hereditary Thrombophilia

What does it mean to have a variant?
Everyone has a unique collection of genetic variants in humans called a DNA code. Most of the variants in this collection are normal and have no known health effects. When these tests find a variant that has been associated with a health condition, it is called a positive result.

Is this answer helpful?

What does my result mean?
The test report includes a result for one variant in the F5 gene and one variant in the F2 gene. The test does not screen variants in other genes.

Your test results are provided as the likelihood of a harmful blood clot for the factors in the test. However, it is not a complete picture of your risk for developing harmful blood clots. Other factors, such as your family history, lifestyle, and medical history, can also affect your risk.

Is this answer helpful?

What does my result mean for me?
The test does not diagnose hereditary thrombophilia. Most people with hereditary thrombophilia never develop thrombosis.

Your test results are provided as the likelihood of a harmful blood clot for the factors in the test. However, it is not a complete picture of your risk for developing harmful blood clots. Other factors, such as your family history, lifestyle, and medical history, can also affect your risk.

Is this answer helpful?

What does my result mean for my family?
Your family members may be at risk for developing harmful blood clots. Sharing your test results with your family members can help them learn their risk.

Is this answer helpful?

What does it mean to have a variant that could not be determined?
The test does not screen all variants that are associated with hereditary thrombophilia. Your test may not be able to determine if both copies of the variant are present. This can be caused by a deletion and can affect how the test interprets and risk level.

Is this answer helpful?

How common is the condition?
Factor V Leiden and the F2 G20210A variant are the most common inherited risk factors for thrombosis in people of European ancestry. Factor V Leiden affects about 5 in 100 people of European ancestry and is found in about 1 in 1,000 people of African ancestry and Asians. The F2 G20210A variant affects about 2 in 100 people of European ancestry and is found in about 1 in 1,000 people of African ancestry and Asians.

Is this answer helpful?

What are the symptoms of harmful blood clots?
Symptoms of harmful blood clots depend on the location of the blood clot. Blood clots in the legs can cause pain, tenderness, swelling, or redness in one or both legs. Blood clots in the chest can cause chest pain or difficulty breathing. Blood clots in the brain can cause sudden vision changes or loss.

Is this answer helpful?

What does it mean to have a variant that could not be determined?
The test does not screen all variants that are associated with hereditary thrombophilia. Your test may not be able to determine if both copies of the variant are present. This can be caused by a deletion and can affect how the test interprets and risk level.

Is this answer helpful?

How is it treated?
Treatment for hereditary thrombophilia usually involves medicines called anticoagulants, which help prevent blood clots from forming or getting larger
